Abstract

Umbelliprenin (UMB), a member 7-prenyloxycoumarins, is a sesquiterpene coumarin produced by several Ferula species; UMB presents diverse properties including anticancer, anti-inflammatory and antioxidant activities. Antihypertensive properties of Ferula extracts were attributed to the sesquiterpene coumarins. This work assessed UMB effect on blood pressure in rats treated with high-fat diet (HFD). Forty Wistar rats were randomly assigned into 5 groups of eight: control group (fed with normal diet), HFD-control (fed with HFD (32% kcal of fat and 1% cholesterol) for 49 days and normal saline on day 50) and three groups of rats fed with HFD for 49 days and treated with UMB 6.25, 12.5 and 25 mg/kg (as a single intraperitoneal dose), on day 50. On day 50, invasive blood pressure measurements were made through cannulation of the carotid artery and use of the PowerLab system. Mean arterial blood pressure (MAP), systolic (SBP) and diastolic (DBP) blood pressure and heart rate (HR) were recorded. SBP and MAP in HFD-control rats were significantly higher than those of the control group (p < 0.001). Moreover, HFD treated rats that received the higher UMB dose showed a significant decrement of SBP and MAP. UMB presented a favourable anti-hypertensive profile in the HFD hypertension model in rats.

Rezumat

Umbelliprenina (UMB) este o cumară cu sâgâră anticanerogeneză, antinfiamatoare și antioxidantă. Proprietățile antihipertensive ale extractelor de Ferula au fost atribuite coumarinelor sesquiterpenice. Această lucrare a evaluat efectul UMB asupra tensiunii arteriale la șobolani tratați cu dietă bogată în grăsime (HFD). Patruzeci de șobolani Wistar au fost repartizați aleatoriu în 5 grupe de opt: grup control (dietă normală), HFD-control (fed cu HFD (32% kcal de grasime și 1% colesterol) timp de 49 de zile și saline normală în ziua 50) și trei grupe de șobolani tratați cu UMB 6.25, 12.5 și 25 mg/kg (dosis intraperitoneală unică) pe ziua 50. Pe ziua 50, tensiunea arterială media (MAP), tensiunea sistolică (SBP) și tensiunea diastolică (DBP) și frecvența cardiacă (HR) au fost înregistrate. SBP și MAP la șobolani-control au fost semnificativ mai mari decât cele ale grupului de control (p < 0.001). De asemenea, tratamentul cu UMB în doză mai mare a fost asociat cu o scădere semnificativă a SBP și MAP. UMB a prezentat un profil favorabil antihipertensiv în modelul de hipertensiune arterială HFD la șobolani.

Keywords: umbelliprenin, systolic blood pressure, mean arterial pressure, high-fat diet, rats

Introduction

Proper management of hypertension as a chronic condition affecting 25% of the general population is of great importance particularly considering the point that a majority of such patients have uncontrolled blood pressure [1, 3]. It was repeatedly shown that hypertension pathophysiology includes a network of multiple interacting vascular effectors. In this context, oxidative stress and endothelial dysfunction were shown in hypertensive individuals and a causal role between them and molecular pathways resulting in hypertension was shown [32]. As primary and adjunctive therapy, the World Health Organization (WHO) emphasizes using non-pharmacological measures (like physical activity) and supplementation with antioxidants by subjects with hypertension [6]. Natural antioxidants are able to protect living organisms from oxidative damage due to overwhelming production of reactive oxygen species (ROS) and consequent lipid
Peroxidation and protein/DNA damage [6, 7, 9, 21, 23, 27, 29, 34-37]. Plants extracts have been widely examined for their possible effects as antihypertensive agents; for instance, *Elaeagnus umbellata* extract was shown to have anti-hypertensive effects (24).

Umbelliprenin (UMB) is a 7-prenyloxycoumarin that is synthesized by many *Ferula* species and presents antioxidant activities. As a sesquiterpene coumarin, UMB has also shown various anti-inflammatory and cancer chemo-preventive activities [13-15, 31]. Another bioactive compound of *Ferula*, aurapetine (7-geranyl-oxy coumarin) has shown anti-hypertensive effects [11, 12].

To the best of our knowledge, possible effects of UMB on hypertension has not yet been reported; so, in the present work, we aimed to assess UMB effects in high-fat diet (HFD)-hypertensive rats.

**Materials and Methods**

**Animals**

Forty male Wistar rats (8 - 10 weeks old) of 200 - 250 g weight, were used in this study. Animals were maintained under standard conditions (at 25°C with 12 h light/12 h dark cycles) and they had free access to food and water. All animal experiments were approved by the animal research Ethics Committee of University of Medical Sciences of Zabol, Iran, and done in accordance with National Institute of Health Guide for the Care and Use of the Laboratory Animals. Animals were randomly assigned into 5 groups of eight rats as follows: control group (fed with normal diet), HFD-control (fed with HFD containing 32% kcal of fat and 1% cholesterol for 49 days and normal saline on day 50) and three groups of rats fed with HFD for 49 days and treated with UMB 6.25, 12.5 and 25 mg/kg (a single intraperitoneal (i.p.) dose), on day 50.

**Reagents**

Umbelliprenin (UMB; Golexir Pars Co., Mashhad, Iran), ketamine (Alfasan, Holland) and xylazine (Pantex, Holland) were used in this work. For measurement of systolic blood pressure (SBP), diastolic blood pressure (DBP), heart rate (HR) and mean arterial blood pressure (MAP), PowerLab (AD Instruments, Bella Vista, New South Wales, Australia) was used [18, 22].

**Oral administration of high-fat diet (HFD)**

Animals were assigned to receive two types of diet (i.e. normal or HFD). The control group received purified low-fat diet (containing 10.6% Kcal of fat) for 7 weeks. The rest of the animals received HFD containing 32% Kcal of fat and 1% cholesterol, for 49 days [4].

**Methods**

After the 7-week period of HFD, animals were fasted overnight (minimum period of 8 - 10 h), and anesthetized using ketamine/xylazine. Animals reflexes were assessed. Animals were placed on a suitable rodent surgical table with electrocardiogram (ECG) recording. The ventral side of the neck, right hind leg, and chest of the animals were carefully disinfected and shaved. A small incision (1.5 - 2.0 cm) was made in rats’ neck for the tracheostomy procedure and carotid artery cannulation. Tracheostomy was done by using a small piece of paediatric Ryle’s tube or rodent tracheal intubation tube as previously described [10]. The carotid artery was identified and the cardiac end of the blood vessel was clamped by a bulldog clamp for cannulation [22]. The blood vessel was cannulated employing a cannula pre-filled with heparinized normal saline (0.5 IU/mL). After cannulation, the bulldog clamp at the cardiac end of the blood vessel, was slowly released [31]. Three hours before cannulation, different doses of UMB were injected i.p. in the HFD-UMB groups while the HFD-control group was treated with normal saline. After cannulation, the sensor was connected to the PowerLab instrument and SBP, DBP, MAP and HR were recorded and analysed using LabChart 8 software [22].

**Statistical analysis**

Data was analysed using SPSS Ver. 11.5 (SPSS, Chicago, IL, USA). Differences among the four groups were assessed using One-way ANOVA followed by Tukey post hoc test. A p < 0.05 is reported as statistically significant.

**Results and Discussion**

*Effects of UMB on systolic blood pressure (SBP) in HFD-hypertensive rats*
As depicted in Figure 1, HFD-control animals, compared to the control group, showed significant increases in SBP (p < 0.001). Among the UMB-treated groups, only UMB 25 mg/kg could significantly decrease HFD-induced SBP (p < 0.001 compared to the HFD-control group).

**Effects of UMB on diastolic blood pressure (DBP) in HFD-hypertensive rats**

As shown in Figure 2, no significant differences were found in DBP between the control and HFD-control groups. Therefore, our results confirmed that DBP was not changed following HFD treatment.

**Effects of UMB on mean arterial pressure (MAP) in HFD-hypertensive rats**

Compared to the control group, as depicted in Figure 3, a significant increase in MAP was found in HFD-control rats (p < 0.001). Furthermore, UMB 25 mg/kg significantly reduced MAP compared to the HFD-control group (p < 0.001). Nevertheless, no significant differences were found between HFD animals receiving lower doses of UMB (6.25 and 12.5 mg) and HFD-control group.

**Effects of UMB on heart rate (HR) in HFD-hypertensive rats**

As depicted in Figure 4, HR did not significantly vary between the control and HFD-treated animals. Further, in the HFD-treated animals, UMB (6.25, 12.5 and 25 mg/kg) treatment did not significantly affect HR.

In the present study, treatment with a single i.p. dose of UMB 25mg/kg, decreased SBP and MAP in HFD-treated hypertensive rats. UMB or 7-prenyloxy-coumarins as sesquiterpene coumarins synthesized by many *Ferula* species and presents diverse effects including anti-inflammatory, antioxidant, cytotoxic, antidiabetic and anti-leishmania effects as well as apoptosis-inducing and anticholinesterase inhibitor properties [25].

One of the most abundant ingredients of *Ferula persica* is UMB. Ghanbari *et al.* assessed the antihypertensive effects of *Ferula persica* in hypertensive rats [5]. They evaluated the acute and chronic effects of different doses of aqueous extract of *F. persica* on hypertensive Wistar rats and found that a single i.v. dose of *F. persica* extract (15 mg/kg) reduced significantly blood pressure levels in hyper-
tensive animals whereas the chronic use of this extract did not have any antihypertensive effect. Furthermore, they found that L-NG-Nitro arginine methyl ester (L-NAME) eliminated and atropine reduced extract’s antihypertensive effects (5). Our findings on the short-term effects of UMB are partially in agreement with the said study showing that UMB, an important ingredient of F. persica, was able to reduce blood pressure levels in a 49-day administration period. Karula et al. investigated the effects of 8 naturally occurring terpenoid and coumarin derivatives from Ferula including UMB, and found that UMB has acetylcholinesterase inhibitory activity [16]. Several studies showed that peripheral and central acetylcholinesterase inhibition could reduce hypertension [17, 30, 33]. One of these studies conducted by Renata et al. confirmed that donepezil, a strong anticholinesterase inhibitor, attenuated hypertension development in spontaneously hypertensive rats, probably due to its anti-inflammatory properties, indicating that acetylcholinesterase inhibition produces beneficial effects for antihypertensive therapy [30]. UMB was isolated from plants of the genus Ferula [6, 19, 20]. One of the said plants is Ferula gummosa. In the study of Mahmoody et al., it was found that supplementation with Ferula gummosa combined with aerobic training in hypertensive rats, significantly augmented the components of the cardiac apelinergic system and reduced oxidative stress in hypertensive rats [19]. The combination of exercise with F. gummosa supplementation increased NO production, which led to a lower blood pressure. One of the active compounds of F. gummosa is UMB which probably contributes to its anti-hypertensive effect. Our findings could be interpreted in part by the findings of the said study on the normalization of oxidative stress markers and the up-regulation of the apelinergic system in hypertensive animals [19]. Nitric oxide synthase inhibition induces hypertension and L-NAME can induce hypertension in animal models. In the study by Moosavi et al., F. gummosa hydroalcoholic extract inhibited renal oxidative stress and inflammation induced by L-NAME [20]. In this model of salt sensitive hypertension, F. gummosa, an abundant source of UMB, reduced the levels of key players of hypertension induction, renal inflammation and oxidative stress.

Prenylated coumarins are naturally occurring compounds found in vegetables which we are daily consumed [8, 28, 36]. UMB is one of these compounds with a structure similar to aurapten (AUR), another prenylated coumarin from Ferula species [38]. The only chemical difference between these two compounds is that the 7-prenyloxy chain is longer [2, 38]. Antihypertensive effects of AUR were reported by previous studies [12, 26]. In rats with hypertension caused by deoxycorticosterone acetate salt, chronic administration of AUR led to a significant blood pressure decrease. At the same time, a single i.v injection of AUR was found to have medium antihypertensive effects in normotensive rats [12, 26]. Considering the chemical similarity of UMB and AUR, antihypertensive properties might be probably a general characteristic of prenylated coumarins.

**Conclusions**

The present study showed the anti-hypertensive effects of UMB and specifically, it indicated that a single i.p. dose of UMB at the concentration of 25 mg/kg significantly diminished blood pressure in HFD-induced hypertensive rats. UMB as a natural product found in several Ferula species, possesses anti-inflammatory and anti-oxidant properties and together with its anti-hypertensive action presented for the first time in the current study, seems to be a very promising compound for further evaluation for management of early stages of hypertension.
