Abstract

Essential oils or volatile oils are natural products that have a large series of uses in the food and cosmetic sectors. According to their intended use, essential oils are subjected to various European guidelines that aim to protect the health and safety of consumers. Volatile oils present important biological activities, some of the most known being their antimicrobial properties, but other potential therapeutic indications for such products have been more recently suggested, as well. However, they are not necessarily harmless and can present an important sensitizing potential. Essential oils have been administered through different routes, including inhalations and skin applications, in the treatment of stress and anxiety. Regardless of the route of administration, aromatherapy deeply relies on the sense of smell and its connection with the limbic system. Nevertheless, outside of the principles of aromatherapy, numerous scientific studies have revealed their potential beneficial implications in Alzheimer’s and other neurological disorders.

Keywords: essential oils, EU legislation, antimicrobial, aromatherapy, central nervous system

Introduction

Essential oils (EOs), also known as volatile oils, are defined in the European Pharmacopoeia as “odorous products” that generally have a complex chemical composition and are obtained from well-defined plant materials through three main processes: steam distillation, dry distillation, or other appropriate mechanical processes that don’t involve heating [14]. They can usually be found in oil cells, glandular hairs, as well as in secretion cavities of different aromatic plants [23].

EOs consist mainly of mixtures of hydrocarbons and their oxygenated derivatives. Taking into account their chemical structure, EOs contain terpenes, which can either be mono-, sesqui- and diterpenes, while tri-terpenes can rarely be detected, and oxygenated compounds such as alcohols, aldehydes, ketones, lactones, acids and esters [40, 49].

Around 3000 EOs have been defined so far, out of which 300 are considered important from a commercial point of view, being widely used in the food and cosmetic industries [41]. EOs can be used through several methods, but they are generally administered in small amounts by inhalation, massage or skin applications, and in rare cases can also be given internally, being found in different supplements or medicines. Inhalation and skin applications of volatile oils have long been utilized in different types of aromatherapy, so as to improve mood and allegedly restore spiritual balance [3].

Many studies have shown the important therapeutic potential that volatile oils possess. Among some of the
most important biological actions noted for these mixtures are the antibacterial, antifungal, antiviral, anti-

oxidant, anti-inflammatory, neuroprotectant and anti-
diabetic activities [31, 43, 56].

Given their pleasant smell, such volatile oils are commonly found in cosmetics, since they cover the unpleasant aroma of different excipients used in the production of such goods [50]. Moreover, volatile oils are also used as such in spa and wellness centres, because of their scent and some of their potential therapeutic effects, as well as for marketing reasons [63]. However, EOs are not necessarily harmless, even though they are natural products. Taking into account the selected administration route, several adverse reactions have been described in the scientific literature. If considering skin applications and inhalation of products containing EOs, different cases of dermatitis and sensitization, as well as respiratory disorders have been reported so far. Moreover, adulteration, as well as incorrect production, storage and labelling of products containing EOs can also lead to clinical manifestations of toxicity [34]. Consequently, the need for appropriate standardization and legislation regarding the use of EOs is essential for keeping consumers safe.

EU legislation on EOs

The major producers of EOs worldwide are China, India, Indonesia, Sri Lanka and Vietnam, while the most important producers in Europe are France and Germany. However, the EU appears to be the world’s main importer of EOs, with France, Germany, and the UK being the most noteworthy traders. Given the growing interest of individuals in pursuing a healthy lifestyle, as well as the increase in the use of EOs in fields ranging from the food sector to the spa industry, a rise in the demand of EOs has been noticed, which is expected to continue growing [9].

In spa and wellness centres, EOs and some of their isolated constituents can be employed in many activities such as aromatherapeutic massages and baths, inhalations, sauna, air aromatization are found in different cosmetic preparations that are used in these health facilities [39]. Some of the most popular EOs used in such centres are those obtained from lavender (Lavandula angustifolia), bergamot (Citrus aurantium var. bergamia), German chamomile (Matricaria chamomilla), eucalyptus (Eucalyptus globulus), frankincense (Boswellia carterii), damask rose (Rosam damascena), tea tree (Malaleuca alternifolia) and peppermint (Mentha piperita var. vulgaris) [24, 50].

Since in wellness centres essential oils are often found in cosmetics, two important EU regulations for such products are represented by the Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH) and the EU Cosmetics Regulation (Regulation (EC) No 1223/2009 of The European Parliament and of The Council) [19]. This last regulation defines the “cosmetic product” as “any substance or mixture intended to be placed in contact with the external parts of the human body (epidermis, hair system, nails, lips and external genital organs) or with the teeth and the mucous membranes of the oral cavity with a view exclusively or mainly to cleaning them, perfuming them, changing their appearance, protecting them, keeping them in good condition or correcting body odours” [47]. As stated, this regulation only focuses on products that interact with the skin and mucous membranes, but mentions that a product meant to be inhaled should not be considered a cosmetic. Annexes II and III of the aforementioned regulation specify which EOs and individual constituents are prohibited for use in cosmetics, as well as certain conditions of use or restrictions concerning such substances or mixtures. Annex III includes 26 potentially allergenic fragrances, most of which are constituents of EOs. Some of the most known fragrances belonging to this list are cinnamonal, citral, citronellol, eugenol, farnesol, geraniol, d-limonene and linalool. For such compounds, it must be declared on the packaging or in the attached or enclosed leaflet if the concentration is higher than 0.01% in rinse-off products such as shower gels and higher than 0.001% in leave-on products such as massage oils and creams [47, 50]. Regarding cosmetic products containing EOs, the Council of Europe has also published several documents with recommendations related to the use of camphor, eucalyptol and menthol, especially in products for infants, which is advised against [21].

The International Fragrance Association (IFRA) also sets certain standards and recommendations regarding the safe use of fragrances. Through its members, IFRA impacts almost 80% of the international fragrance industry in terms of production volume [58]. At European level, IFRA works on issuing important guidelines (e.g. EFEO/IFRA Guidelines on Substance Identification and Sameness of Natural Complex Substances (NCS) under REACH and CLP) together with one of its partners, the European Federation of Essential Oils (EFEO), which is a non-profit association that aims to protect and encourage the production and trade of EOs and related products throughout the continent [22].

Important quality requirements of EOs are also set through International Organization for Standardization (ISO) standards. There are more than 100 published ISO standards under the direct responsibility of ISO/TC 54 that is in charge of the standardization of the analysis methods and specifications for EOs. Such standards refer to general rules for packaging, storage, labelling, determination of various characteristics (e.g. refractive index, optical rotation, miscibility in ethanol), as well as to content evaluation [55].

It is important to mention that if the product containing EOs cannot be included in the description of a cosmetic product, then it will only be regulated by the General Products Safety Directive (Directive 2001/95/EC of the European Parliament and of the Council of 3
reported several other biological activities that are in a close relationship with the chemical composition of EOs obtained from different species. Effects of EOs may also vary depending on the route of administration: oral, topical or inhalation. Table I includes beneficial activities of EOs frequently used in wellness centres. Given the subject covered by the present work, only in vivo studies focusing on topical administration and inhalation were selected. A large number of EOs showed a broad-spectrum inhibitory activity over microorganisms, as demonstrated by in vitro tests against several types of human pathogens. Some of these EOs were obtained from species such as Artemisia cana, Achillea clavennae, Cyperus longus, Copaifera officinalis, Foeniculum vulgare, Juniperus phoenicea, Mentha piperita, Nigella sativa, Pimpinella anisum, Rosmarinus officinalis, Salvia officinalis and Syzygium aromaticum [56]. Having such exceptional antimicrobial activities, several EOs were already tested, showing promising results regarding their applicability as preservatives in cosmetic formulations, alone or in combination with synthetic preservatives. These EOs were obtained from species such as Artemisia afra, Calamintha officinalis, Laurus nobilis, Eucalyptus globulus and Salvia officinalis [18].

### Benefits vs. toxicity of EOs

It is well known that EOs have many biological activities, out of which their antibacterial, antifungal and antiviral properties are the most frequently mentioned. They are also characterized by having an intense skin permeation capacity, being often used as sorption promoters for drugs [56]. Apart from these, literature

However, apart from these valuable properties, EOs may also possess a rather significant toxicity potential. Therefore, in order to ensure only human health improvement and well-being for EOs usage, strict regulations regarding their use are needed.
convulsions in children aged between 2 months and 6 years [42]. Furthermore, cutaneous toxicity of EOs is more frequently reported and has been known for a very long period of time. The phenomena that may appear could be phototoxic dermatoses or allergic contact dermatitis. Phototoxic reactions occur mainly as a consequence of psoralens or furanocoumarins that are present in some EOs followed by a skin reaction enhanced by heat, humidity and sun/UV light exposure. For example, bergamot and other citrus oil skin applications may frequently cause berloque dermatitis. Moreover, bergamot EO contains a compound called 5-methoxypsoralen (bergapten), which in combination with UV-light exposure was observed to induce skin cancer [4]. Other EOs found to be responsible for potential phototoxic dermatoses are cedarwood, rosemary, eucalyptus, petitgrain, neroli, yarrow, anise and ylang-ylang [34]. As for the allergic episodes, there are several compounds in EOs that were found to have an allergenic potential, out of which there are already 26 known allergens of odorous substances that must be mentioned on the list of ingredients for cosmetic products [61]. These substances were already mentioned in the first part of the article and are included in annex III of the Regulation (EC) No 1223/2009. Another important aspect for the safe use of EOs is their storage, as it is already known that oxidation of some of their components in the presence of light, air and humidity may enhance their toxic properties. Several studies conducted by Hausen et al. on tea tree EO suggest that the oxidation forms that appear during prolonged storage are the main allergenic factors. Moreover, the freshly distilled tea tree EO did not show any sensitizing capacity. The same authors concluded that the tea tree EO components that could be responsible for the allergic reaction were: terpinolene, α-terpineol, ascaridole and 1,2,4-trihydroxymethane [26, 27]. Taking these aspects into consideration, EOs should always be stored in the refrigerator or in a cold, dark place [34]. For the safe use of EOs, a well-balanced risk-benefit assessment is crucial to be defined, but given their complex chemical composition and great variability, this task represents a great challenge for scientists and health policy authorities.

Aromatherapy and how EOs impact the central nervous system

“Aromatherapy” is a notion which commonly describes the use of EOs in skin massages or in the ambient air. However, medical aromatherapy has a more precise definition and states that the sole purpose of using such a method is to determine a psychological and physiological reaction of the organism [52]. The last decade revealed increased medical interest in aromatherapy and nowadays conventional medicine does not regard this method as pseudoscientific anymore [3, 17, 52]. This is due to the fact that it becomes more and more obvious that aromatherapy can have a great influence upon major organ systems like the central nervous system and there are several studies that reach such conclusions [1, 17, 30]. Through inhalation or massages, EOs penetrate the skin and mucosa. Once they enter the systemic circulation, they are also able to reach the brain and even cross the blood brain barrier. EOs constituents can therefore be in direct contact with important nervous structures and modulate the function of neurons [1, 3, 15]. It appears that active compounds from EOs with small molecular size and high lipophilicity, such as certain terpenes, have the highest brain blood barrier penetration. This information is valuable because it can help further research focus on this type of compounds, which apparently have a greater impact on the central nervous system [1, 2].

The antioxidant role of EOs plays an important part in neuroprotection [2]. Oxidative stress is deeply involved in the pathogenesis of Alzheimer’s disease, in which certain pathophysiologic mechanisms such as β-amyloid induced neural loss, mitochondrial dysfunction and accumulation of tau associated neurofibrillary tangles can be observed [10]. Such EOs with antioxidant properties are those obtained from Cinnamomum zeylanicum, Ocimum basilicum, Pinus halepensis, Prunus dulcis, Salvia officinalis, Lavandula angustifolia and Juniperus communis [10-13, 20, 25, 45, 57]. It must be mentioned that their antioxidant property is not only valued in relation to Alzheimer’s disease, but their use also shows great promise in the treatment of other types of dementias and neurodegenerative diseases and even in mild cognitive impairment. The fact that EOs seem to be able to slow down the pathogenesis of neurological diseases that are linked to oxidative stress could be a step forward for the prevention of these diseases. However, further studies are required in order to demonstrate that using EOs and practicing aromatherapy on a regular basis has a significant impact in delaying the progression of these conditions or even help in preventing or stopping their evolution [10, 64, 66]. Besides their action on oxidative stress, EOs also seem to inhibit cholinesterases. This is important because in Alzheimer’s disease and other types of dementia there is a depletion of acetylcholine. Studies have shown that the effect EOs have on acetylcholinesterase or butyrylcholinesterase leads to the inhibition of the hydrolytic degradation of acetylcholine and, by doing so, the levels of this neurotransmitter are increased. The conventional therapeutic strategy in Alzheimer’s disease focuses on drugs such as rivastigmine and donepezil, which have an inhibitory action on cholinesterases. Using EOs that have the same effect could lower the doses needed for conventional drugs. Furthermore, EOs could also be used for those patients who cannot tolerate the adverse effects of the commonly
prescribed medication [7, 10, 37]. The inhibition of cholinesterases has been proved for EOs such as those extracted from: Juniperus communis, Salvia leriifolia, Polygonum hydropiper, Citrus limonum and Mentha spicata [5-7, 12, 35].

Regardless of the route of administration of EOs (inhalation or skin massages), aromatherapy deeply relies on the sense of smell and its connection with the limbic system. From the primary olfactory cortex there are projections to important structures, such as the orbital prefrontal cortex, amygdala, hypothalamus, basal ganglia and hippocampus. Through olfaction, EOs can therefore trigger modifications in those structures in the brain which dictate human behaviour, the functioning of the autonomic nervous system and pain perception [52, 53]. The modulation of nociception by EOs at the central nervous system level is far from being understood. The hypothesis is that compounds from these oils influence glutamatergic transmission and inhibit the a-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA), N-methyl-D-aspartic acid (NMDA) and kainate receptors. Experimental models have shown that Lavandula angustifolia, Salvia sclareae and Mentha spicata EOs possess analgesic action and could be used in those diseases that involve chronic pain [17, 36]. In what concerns the autonomic nervous system, it appears that Juniperus communis EO increases the parasympathetic activity and this has important consequences, such as reducing heart rate and blood pressure. This proves that aromatherapy is a viable treatment strategy for people with increased sympathetic activity like those suffering from anxiety [44]. The anxiolytic effect seems to be connected to the γ-aminobutyric acid A (GABA[A]) receptor at least for some EOs, like the one obtained from Ferulago angulata [8]. It must be noted that when the EO is administered by skin massages, the sense of touch and the sensory pathways also become important and the anxiolytic effect is emphasized. This form of administration was shown to significantly help with behavioural and psychological symptoms of dementia [65]. Other EOs can induce a state of anxiety, producing a raise in blood pressure or breathing rate by increasing the sympathetic activity. Their use should be avoided in people with anxiety, but they can be useful in various conditions, for example in treating hypotension. One such oil which increases sympathetic activity is Jasminum sambac EO [28].

In addition to the aforementioned effects of EOs, the anticonvulsive properties (some of them) possess and their benefits in sedation and sleep should be noted. Plants containing volatile oils with such properties are Ocimum basilicum and Rosa damascene [17]. The impact of aromatherapy on the central nervous system is yet to be understood and more clinical trials need to be conducted, given that many experiments on animal models proved successful. Many EOs that are already being used in wellness centres were shown to have properties that can influence the brain and help in several neurological conditions. The mechanism of action of such substances in the central nervous system is very complex and can vary a lot from one EO to another. Consequently, taking a step further into characterizing the action of such oils on human subjects, as well as refining the concept of “medical aromatherapy” and standardizing the method in which it can be applied in spa and wellness centres and rehabilitation clinics could prove to be extremely beneficial for the general healthcare [3, 52].

Conclusions

EOs have long been used in different therapeutic approaches over centuries, due to their biological properties, such as antibacterial, antifungal and antiviral. Nonetheless, recent studies have also emphasized the benefit of the use of such oils for different neurological and cardio-vascular conditions as well. However, such mixtures, or their isolated compounds can also possess a significant toxicity potential, especially when misused. Therefore, different types of guidelines and regulations are now available throughout the European Union which are meant to keep consumers safe. Moreover, further clinical studies could deepen our knowledge on how EOs impact the human body and how they could be more appropriately and frequently used for the treatment or prevention of different diseases, in accordance with their proven efficacy.
